Quick Security Audit Results

This quick audit identifies common security issues on your site.

Please note that there are many ways data and security can be compromised, and not all of them can be detected automatically. If you're concerned about your website security, we recommend a more in-depth manual audit for comprehensive protection.

DNS Protection

Your site has DNS protection. This is good for security, speed and SEO and you have the best protection against bots and DDoS attacks.

WordPress

Your site is built with WordPress. This is a widely-used, powerful CMS. With proper maintenance and the right security plugins, you can significantly enhance its security.

WordPress Version

Your WordPress version is up to date. Keeping the core updated is one of the most important things you can do for security and performance.

SSL

Your site is protected by SSL. This is good for security and SEO and you should check that non-ssl traffic is redirected to SSL automatically.

Login Protection

We did not detect any common issues with leaked user logins. This is good, as we do not want to give too much information to bots.

Site Hardening

We detected some basic hardening on your site which is great.

2024-11-08 11:54:42

Data Leakage

We did not detect any common data leakage on your site. Common leakage happens in upload folders, old versions of the website and from backup plugins that are badly configured.

Bot Management

We detected a bots.txt file on your site. This is a good start but there is always room for improvement when hardening against bots.
